Binary search trees

Definition. A BST is a binary tree in symmetric order.

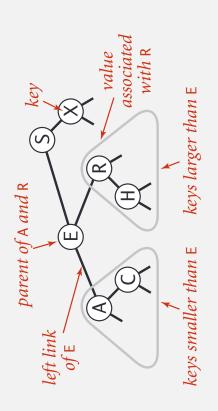

A binary tree is either:

- × Empty.
- Two disjoint binary trees (left and right).

Symmetric order. Each node has a key, and every node's key is:

- Larger than all keys in its left subtree.
- * Smaller than all keys in its right subtree.

BST representation in Java

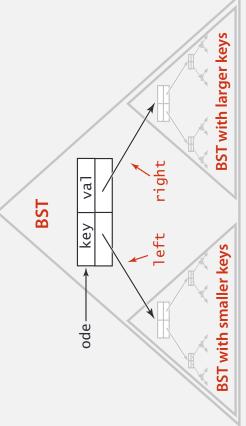

Java definition. A BST is a reference to a root Node.

A Node is comprised of four fields:

- A Key and a Value.
- * A reference to the left and right subtree.

```
m{f} smaller keys
```

```
private class Node
{
   private Key key;
   private Value val;
   private Node left, right;
   public Node(Key key, Value val)
   {
     this.key = key;
     this.val = val;
}
}
```

Binary search tree

Key and Value are generic types; Key is Comparable

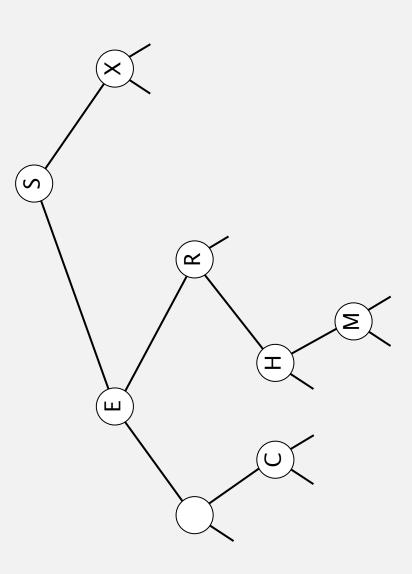

BST implementation (skeleton)

```
root of BST
public class BST<Key extends Comparable<Key>, Value>
                                                                                                                                                                                                                   public void put(Key key, Value val)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           public Iterable<Key> iterator()
                                                                                                                                                      { /* see previous slide */ }
                                                                                                                                                                                                                                                    { /* see next slides */ }
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             { /* see next slides */ }
                                                                                                                                                                                                                                                                                                                                                                                                                                              { /* see next slides */ }
                                                                                                                                                                                                                                                                                                                                                 { /* see next slides */ }
                                                                                                                                                                                                                                                                                                                                                                                                             public void delete(Key key)
                                                                                                                                                                                                                                                                                                                 public Value get(Key key)
                                                          private Node root;
                                                                                                                       private class Node
```

Binary search tree demo

Search. If less, go left; if greater, go right; if equal, search hit.

successful search for H

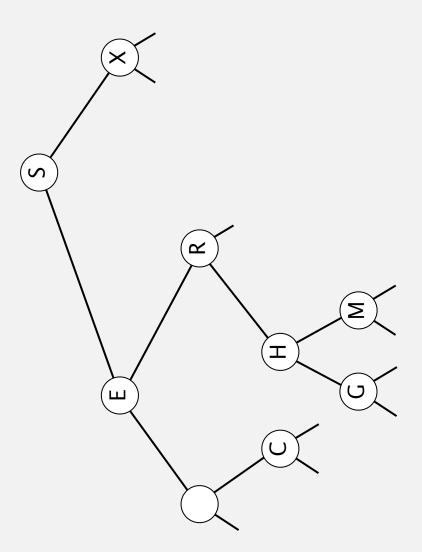

_

Binary search tree demo

Insert. If less, go left; if greater, go right; if null, insert.

insert G

BST search: Java implementation

Get. Return value corresponding to given key, or null if no such key.

```
public Value get(Key key)
                           while (x != nul)
                Node x = root;
                                                                                            return null;
```

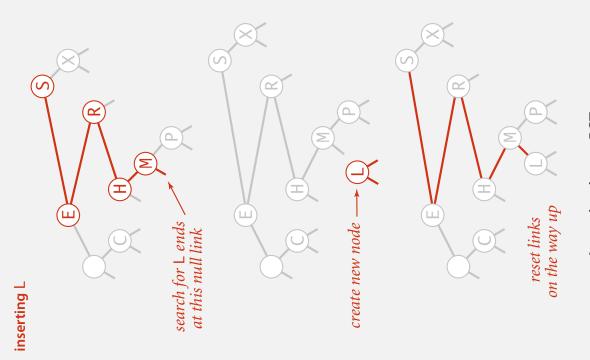

Cost. Number of compares is equal to 1 + depth of node.

BST insert

Put. Associate value with key.

Search for key, then two cases:

- x Key in tree ⇒ reset value.
- x Key not in tree ⇒ add new node.

Insertion into a BST

BST insert: Java implementation

Put. Associate value with key.

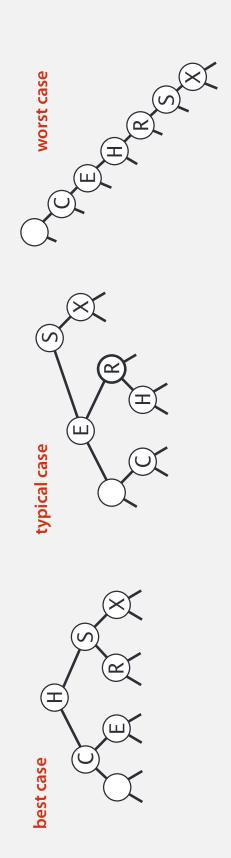

```
concise, but tricky,
                          recursive code;
                                                  read carefully!
                                                                                                                   private Node put(Node x, Key key, Value val)
                                                                                                                                                                           if (x == null) return new Node(key, val);
                                                                                                                                                                                                                                                                 x.left = put(x.left, key, val);
else if (cmp > 0)
                                                                                                                                                                                                                                                                                                                             x.right = put(x.right, key, val);

                                                                                                                                                                                                           int cmp = key.compareTo(x.key);
if (cmp < 0)</pre>
                                                      { root = put(root, key, val); }
                                                                                                                                                                                                                                                                                                                                                             else if (cmp == 0)
                                                                                                                                                                                                                                                                                                                                                                                        x.val = val;
                                                                                                                                                                                                                                                                                                                                                                                                                           return x;
```

Cost. Number of compares is equal to 1 + depth of node.

\equiv

Tree shape

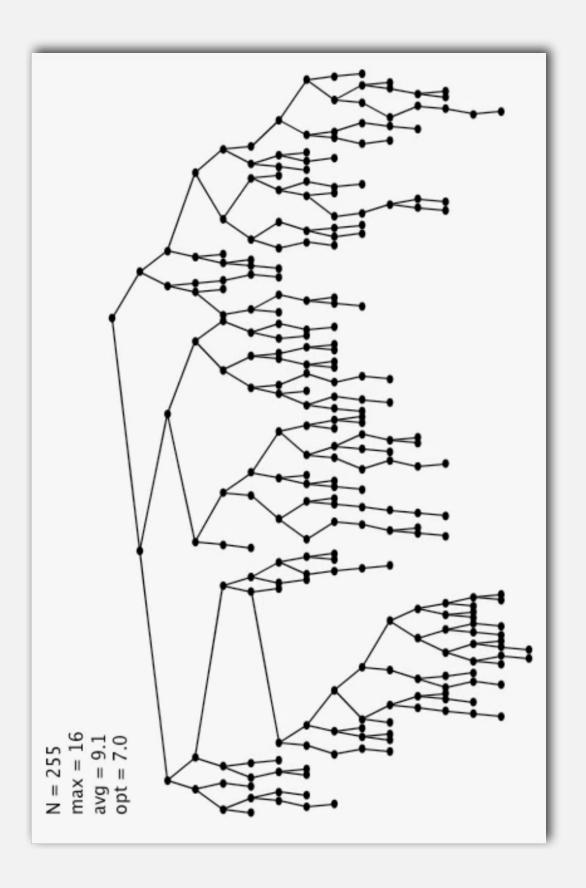

- * Many BSTs correspond to same set of keys.
- * Number of compares for search/insert is equal to 1 + depth of node.

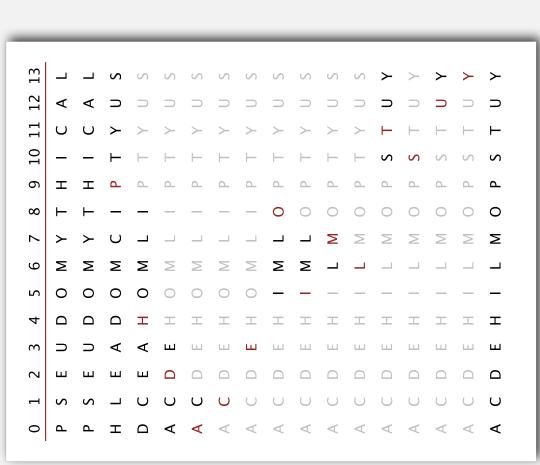

Remark. Tree shape depends on order of insertion.

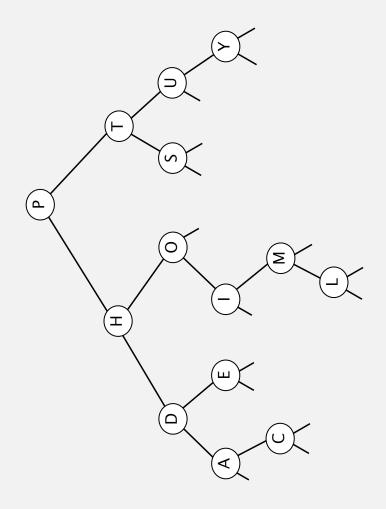

BST insertion: random order visualization

Ex. Insert keys in random order.

Correspondence between BSTs and quicksort partitioning

Remark. Correspondence is 1-1 if array has no duplicate keys.

BSTs: mathematical analysis

Proposition. If N distinct keys are inserted into a BST in random order, the expected number of compares for a search/insert is $\sim 2 \ln N$. Pf. 1-1 correspondence with quicksort partitioning. Proposition. [Reed, 2003] If N distinct keys are inserted in random order, expected height of tree is $\sim 4.311 \ln N$.

How Tall is a Tree?

Bruce Reed CNRS, Paris, France reed@moka.ccr.jussieu.fr

ABSTRACT

Let H_n be the height of a random binary search tree on n nodes. We show that there exists constants $\alpha = 4.31107...$ and $\beta = 1.95...$ such that $\mathbf{E}(H_n) = \alpha \log n - \beta \log \log n + O(1)$, We also show that $\operatorname{Var}(H_n) = O(1)$.

3ut... Worst-case height is N.

(exponentially small chance when keys are inserted in random order)

Minimum and maximum

Minimum. Smallest key in table.

Maximum. Largest key in table.

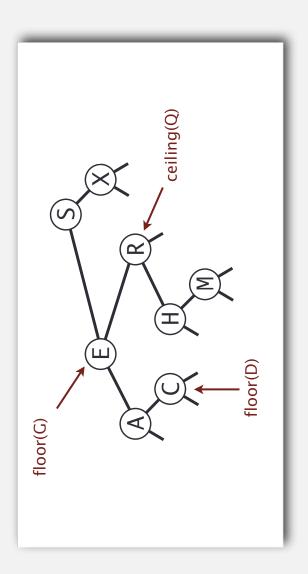

Q. How to find the min / max?

Floor and ceiling

Floor. Largest key ≤ a given key.

Ceiling. Smallest key ≥ a given key.

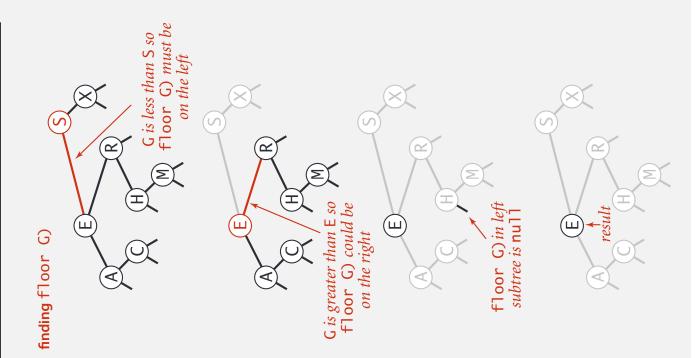

Q. How to find the floor / ceiling?

Computing the floor

Case 1. [k equals the key at root] The floor of k is k.

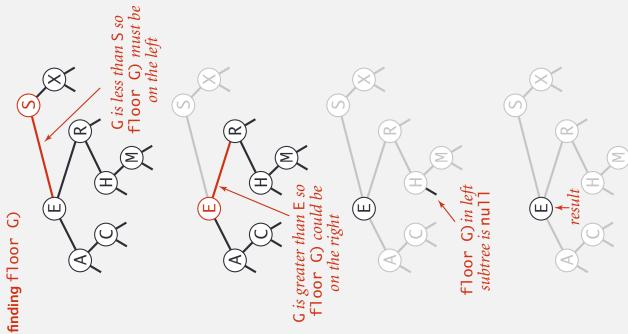

Case 2. [k is less than the key at root] The floor of k is in the left subtree.

Case 3. [k is greater than the key at root] The floor of k is in the right subtree (if there is any key $\leq k$ in right subtree); otherwise it is the key in the root.

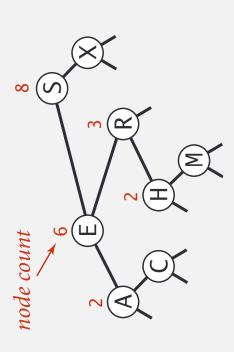

Computing the floor

```
if (cmp < 0) return floor(x.left, key);</pre>
                                                                                                                                                                                 private Node floor(Node x, Key key)
                                                                                                                                                                                                                                                                            int cmp = key.compareTo(x.key);

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            return x;
                                                                                                                                                                                                                                                                                                                                       if (cmp == 0) return x;
public Key floor(Key key)
                                                                                                                       return x.key;
```

Subtree counts

In each node, we store the number of nodes in the subtree rooted at that node; to implement size(), return the count at the root.

Remark. This facilitates efficient implementation of rank() and select().

BST implementation: subtree counts

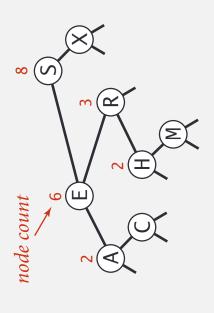

```
when x is null
                                                                                                                                                      ok to call

```

Rank

Rank. How many keys < k?

Easy recursive algorithm (3 cases!)

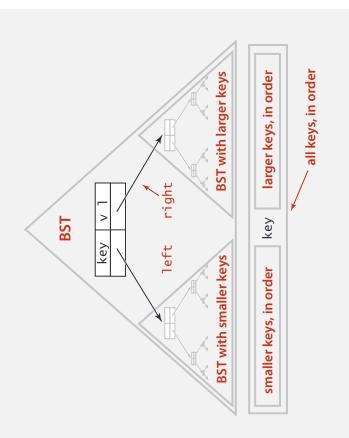

```
else if (cmp > 0) return 1 + size(x.left) + rank(key, x.right);
                                                                                                                                                                                                                                                          (cmp < 0) return rank(key, x.left);</pre>
                                                                                                                                                                                                                                                                                                                                   else if (cmp == 0) return size(x.left);
                                                                                                                                                                                                             int cmp = key.compareTo(x.key);
                                                                                                            private int rank(Key key, Node x)
                                     { return rank(key, root); }
                                                                                                                                                                             if (x == null) return 0;
public int rank(Key key)
```

Inorder traversal

- Traverse left subtree.
- Enqueue key.
- Traverse right subtree.

```
public Iterable<Key> keys()
{
   Queue<Key> q = new Queue<Key>();
   inorder(root, q);
   return q;
}
private void inorder(Node x, Queue<Key> q)
{
   if (x == null) return;
   inorder(x.left, q);
   q.enqueue(x.key);
   inorder(x.right, q);
}
```

Property. Inorder traversal of a BST yields keys in ascending order.

Next. Deletion in BSTs.

2

BST deletion: lazy approach

To remove a node with a given key:

- Set its value to null.
- * Leave key in tree to guide search (but don't consider it equal in search).

Cost. $\sim 2 \ln N'$ per insert, search, and delete (if keys in random order), where N' is the number of key-value pairs ever inserted in the BST.

Unsatisfactory solution. Tombstone (memory) overload.

Deleting the minimum

To delete the minimum key:

Go left until finding a node with a null left link.

reaching null go left until

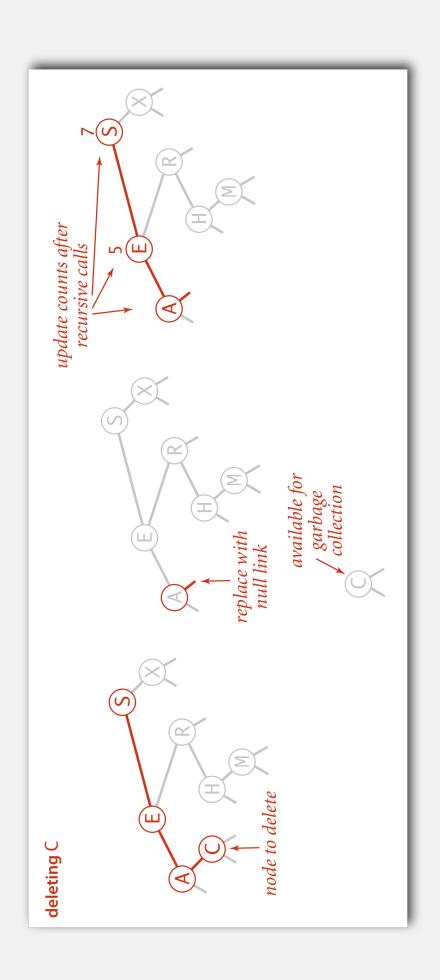

- Replace that node by its right link.

Hibbard deletion

To delete a node with key k: search for node t containing key k.

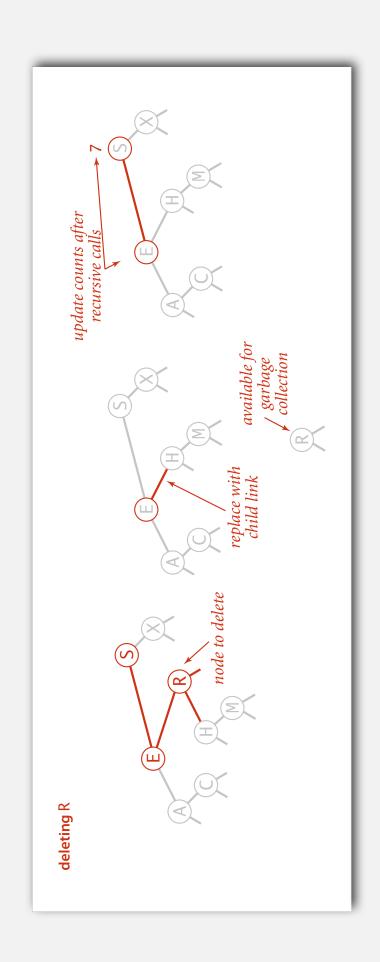

Case 0. [0 children] Delete t by setting parent link to null.

Hibbard deletion

To delete a node with key k: search for node t containing key k.

Case 1. [1 child] Delete t by replacing parent link.

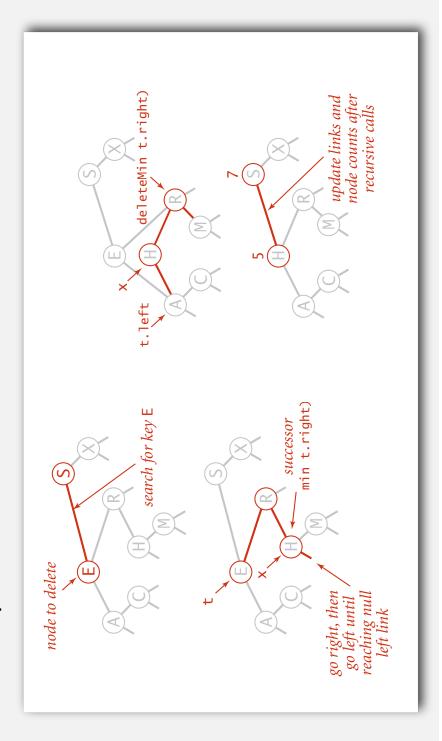

Hibbard deletion

To delete a node with key k: search for node t containing key k.

Case 2. [2 children]

- Find successor x of t.
- Delete the minimum in t's right subtree.
- x Put x in t's spot.

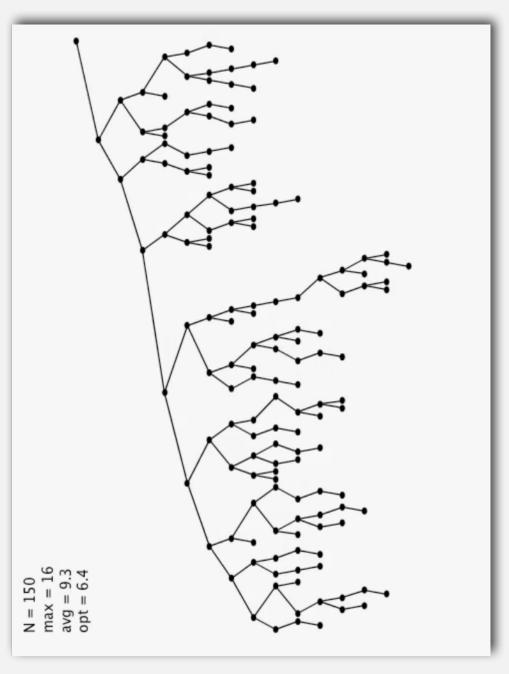

Hibbard deletion: Java implementation

```
search for key
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          update subtree

```

Hibbard deletion: analysis

Unsatisfactory solution. Not symmetric.

Longstanding open problem. Simple and efficient delete for BSTs. Surprising consequence. Trees not random (!) \Rightarrow sqrt (N) per op.

ST implementations: summary

		guarantee	4 1	ช	average case		ordered	operations
search insert	inse	ırı	delete	search hit	insert	delete	iteration?	on keys
z	z		z	N/2	z	N/2	OL OL	equals()
N BI	z		z	N g	N/2	N/2	yes	compareTo()
z	z		Z	1.39 lg N	N 91 95.1	N N	yes	compareTo()

other operations also become \sqrt{N} if deletions allowed

Next lecture. Guarantee logarithmic performance for all operations.
