2.3 QUICKSORT

- quicksort
- selection
- duplicate keys
- system sorts

Two classic sorting algorithms

Critical components in the world's computational infrastructure.

- Full scientific understanding of their properties has enabled us to develop them into practical system sorts.
- Quicksort honored as one of top 10 algorithms of 20th century in science and engineering.

Mergesort.

--- last lecture

- Java sort for objects.
- Perl, C++ stable sort, Python stable sort, Firefox JavaScript, ...

Quicksort.

this lecture

- Java sort for primitive types.
- C qsort, Unix, Visual C++, Python, Matlab, Chrome JavaScript, ...

Quicksort t-shirt

2.3 QUICKSORT

quicksort

Selection

duplicate key

Algorithms

> system sorts

Robert Sedgewick | Kevin Wayne

http://algs4.cs.princeton.edu

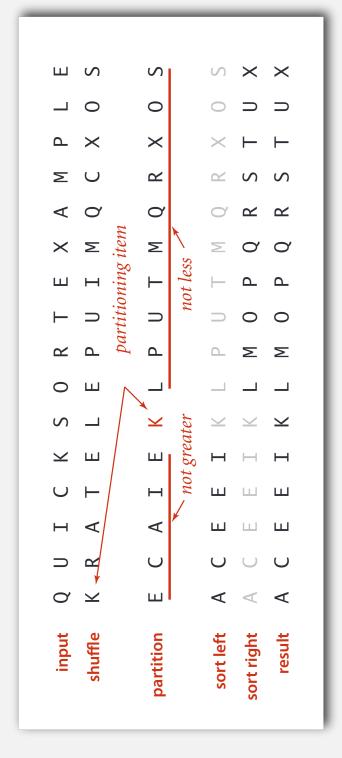

Quicksort

Basic plan.

- Shuffle the array.
- Partition so that, for some j
- entry a[j] is in place
- no larger entry to the left of j
- no smaller entry to the right of j
- Sort each piece recursively.

Sir Charles Antony Richard Hoare 1980 Turing Award

u

Quicksort partitioning demo

Repeat until i and j pointers cross.

- x Scan i from left to right so long as (a[i] < a[lo]).</p>
- x Scan j from right to left so long as (a[j] > a[lo]).
- x Exchange a[i] with a[j].

1.2

Quicksort: implementation details

Partitioning in-place. Using an extra array makes partitioning easier (and stable), but is not worth the cost. Terminating the loop. Testing whether the pointers cross is a bit trickier than it might seem.

Staying in bounds. The (j == 10) test is redundant (why?), but the (i == hi) test is not. Preserving randomness. Shuffling is needed for performance guarantee.

Equal keys. When duplicates are present, it is (counter-intuitively) better to stop on keys equal to the partitioning item's key.

Quicksort: empirical analysis

Running time estimates:

- * Home PC executes 108 compares/second.
- * Supercomputer executes 10¹² compares/second.

(N	billion	12 min	instant
quicksort (N log N)	million	0.6 sec	instant
gui	thousand	instant	instant
g N)	billion	18 min	instant
mergesort (N log N)	million	1 second	instant
mer	thousand	instant	instant
N ²)	billion	2.8 hours 317 years	1 week
insertion sort (N²)	million	2.8 hours	1 second
sui	computer thousand	instant	instant
	computer	home	super

Lesson 1. Good algorithms are better than supercomputers. Lesson 2. Great algorithms are better than good ones.

Quicksort: best-case analysis

Best case. Number of compares is $\sim N \lg N$.

Quicksort: average-case analysis

Proposition. The average number of compares $C_{\mathbb N}$ to quicksort an array of N distinct keys is $\sim 2N \ln N$ (and the number of exchanges is $\sim \frac{1}{2} N \ln N$).

Pf. C_N satisfies the recurrence $C_0 = C_1 = 0$ and for $N \ge 2$:

$$C_N = \begin{array}{c} \text{partitioning} \\ \downarrow \\ \downarrow \\ V \\ N+1) + \left(\frac{C_0 + C_{N-1}}{N} \right) + \left(\frac{C_1 + C_{N-2}}{N} \right) + \ldots + \left(\frac{C_{N-1} + C_0}{N} \right) \\ \end{array}$$

 \star Multiply both sides by N and collect terms:

partitioning probability

$$NC = N N + 1 + 2 C + C_1 + + C_1$$

* Subtract this from the same equation for N-1:

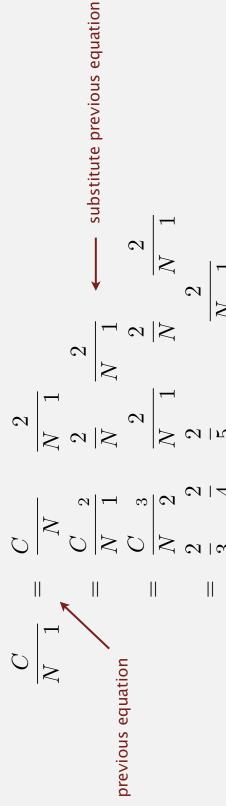

$$N \quad 1) \qquad = 2N + 2$$

* Rearrange terms and divide by N(N+1):

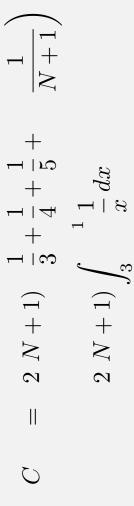

$$\frac{N}{N-1} = \frac{2}{N-1}$$

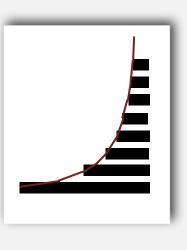

Quicksort: average-case analysis

* Repeatedly apply above equation:

* Approximate sum by an integral:

x Finally, the desired result:

$$2 N + 1) \ln N \approx 139 N \lg N$$

Quicksort: summary of performance characteristics

Worst case. Number of compares is quadratic.

$$N + (N-1) + (N-2) + ... + 1 \sim \frac{1}{2}N^2$$

More likely that your computer is struck by lightning bolt.

Average case. Number of compares is $\sim 1.39 \, N \lg N$.

- 39% more compares than mergesort.
- But faster than mergesort in practice because of less data movement.

Random shuffle.

- Probabilistic guarantee against worst case.
- * Basis for math model that can be validated with experiments.

Caveat emptor. Many textbook implementations go quadratic if array

- Is sorted or reverse sorted.
- Has many duplicates (even if randomized!)

Quicksort properties

Proposition. Quicksort is an in-place sorting algorithm.

* Partitioning: constant extra space.

* Depth of recursion: logarithmic extra space (with high probability).

can guarantee logarithmic depth by recurring on smaller subarray before larger subarray

Proposition. Quicksort is not stable.

Quicksort: practical improvements

Insertion sort small subarrays.

- * Even quicksort has too much overhead for tiny subarrays.
- × Cutoff to insertion sort for ≈ 10 items.
- * Note: could delay insertion sort until one pass at end.

```
private static void sort(Comparable[] a, int lo, int hi)
                                                                                                       Insertion.sort(a, lo, hi);
                                                                                                                                                                                        int j = partition(a, lo, hi);
                                                   if (hi \leftarrow lo + CUTOFF - 1)
                                                                                                                                                                                                                 sort(a, lo, j-1);
sort(a, j+1, hi);
                                                                                                                                        return;
```

Quicksort: practical improvements

Median of sample.

- » Best choice of pivot item = median.
- * Estimate true median by taking median of sample.
- x Median-of-3 (random) items.

```
12/7 N In N compares (slightly fewer)12/35 N In N exchanges (slightly more)
```

```
private static void sort(Comparable[] a, int lo, int hi)
                                                                                                       int m = medianOf3(a, lo, lo + (hi - lo)/2, hi);
swap(a, lo, m);
                                                                                                                                                                                 int j = partition(a, lo, hi);
sort(a, lo, j-1);
sort(a, j+1, hi);
                                               if (hi <= lo) return;
```

Selection

Goal. Given an array of N items, find a k^{th} smallest item.

Ex. Min (k = 0), max (k = N - 1), median (k = N/2).

Applications.

- order statistics.
- × Find the "top k."

Use theory as a guide.

- \star Easy $N\log N$ upper bound. How?
- × Easy *N* upper bound for k = 1, 2, 3. How?
- * Easy N lower bound. Why?

Which is true?

- $\star N \log N$ lower bound?
- \star N upper bound?
- is selection as hard as sorting?

Quick-select

Partition array so that:

- Entry a[j] is in place.
- No larger entry to the left of j.
- » No smaller entry to the right of j.

Repeat in one subarray, depending on j; finished when j equals k.

```
if a[k] is here
                                               set lo to j+1
                                                                                                          >
∧I
                                if a[k] is here
                                             set hi to j-1
public static Comparable select(Comparable[] a, int k)
{
                                                                                                 return a[k];
                                                       int lo = 0, hi = a.length - 1;
                                        StdRandom.shuffle(a);
                                                                      while (hi > lo)
                                                                                                                                                                               return a[k];
                                                                                                                                                 else
```

Quick-select: mathematical analysis

Proposition. Quick-select takes linear time on average.

Pf sketch.

* Intuitively, each partitioning step splits array approximately in half:

$$N + N/2 + N/4 + ... + 1 \sim 2N$$
 compares.

* Formal analysis similar to quicksort analysis yields:

$$C_N = 2 N + 2 k \ln (N/k) + 2 (N-k) \ln (N/(N-k))$$

(2 + 2 ln 2) N to find the median

(as with quicksort) the random shuffle provides a probabilistic guarantee. Remark. Quick-select uses $\sim 1/2 N^2$ compares in the worst case, but

Theoretical context for selection

Proposition. [Blum, Floyd, Pratt, Rivest, Tarjan, 1973] Compare-based selection algorithm whose worst-case running time is linear.

```
by.

Manuel Blum, Robert W. Floyd, Vaughan Pratt,
Ronald L. Rivest, and Robert E. Tarjan

Abstract

The number of comparisons required to select the i-th smallest of
n numbers is shown to be at most a linear function of n by analysis of
a new selection algorithm -- PICK. Specifically, no more than
5.4505 n comparisons are ever required. This bound is improved for
```

Remark. But, constants are too high \Rightarrow not used in practice.

Use theory as a guide.

- * Still worthwhile to seek practical linear-time (worst-case) algorithm.
- Until one is discovered, use quick-select if you don't need a full sort.

Duplicate keys

Often, purpose of sort is to bring items with equal keys together.

- Sort population by age.
- Remove duplicates from mailing list.
- Sort job applicants by college attended.

Typical characteristics of such applications.

- x Huge array.
- Small number of key values.

Duplicate keys

Mergesort with duplicate keys. Between $\frac{1}{2}N\lg N$ and $N\lg N$ compares.

Quicksort with duplicate keys.

- Algorithm goes quadratic unless partitioning stops on equal keys!
- * 1990s C user found this defect in qsort().

Duplicate keys: the problem

Mistake. Put all items equal to the partitioning item on one side. Consequence. $\sim 1/2 N^2$ compares when all keys equal.

BAABABBBCCC

Recommended. Stop scans on items equal to the partitioning item. Consequence. $\sim N \lg N$ compares when all keys equal.

BAABABCCBCB

A A A A A A A A A A

Desirable. Put all items equal to the partitioning item in place.

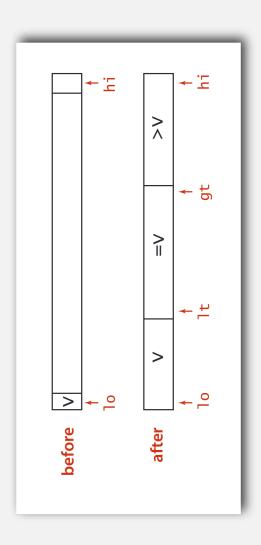

AAABBBBBCCC

AAAAAAAAAAA

3-way partitioning

Goal. Partition array into 3 parts so that:

- * Entries between 1t and gt equal to partition item v.
- No larger entries to left of 1t.
- No smaller entries to right of gt.

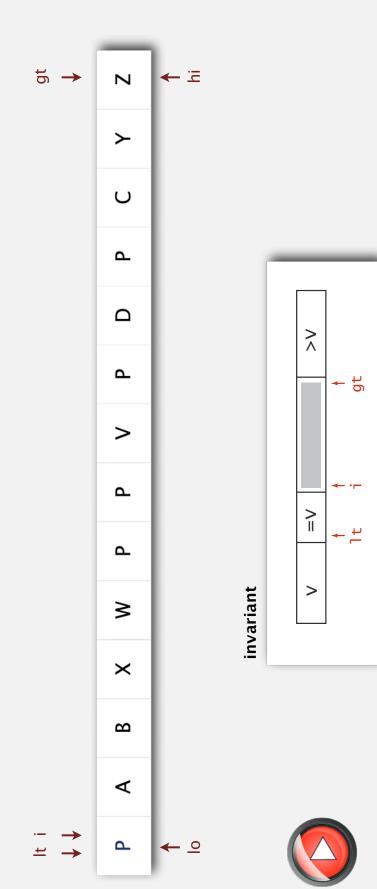

Dutch national flag problem. [Edsger Dijkstra]

- x Conventional wisdom until mid 1990s: not worth doing.
- * New approach discovered when fixing mistake in C library qsort().
- Now incorporated into qsort() and Java system sort.

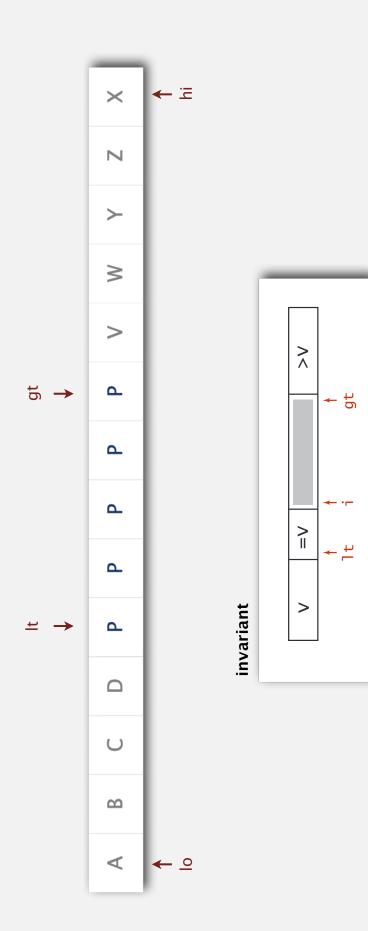

Dijkstra 3-way partitioning demo

- Let v be partitioning item a[lo].
- x Scan i from left to right.
- (a[i] < v): exchange a[lt] with a[i]; increment both lt and i
- (a[i] > v): exchange a[gt] with a[i]; decrement gt
- (a[i] == v): increment i

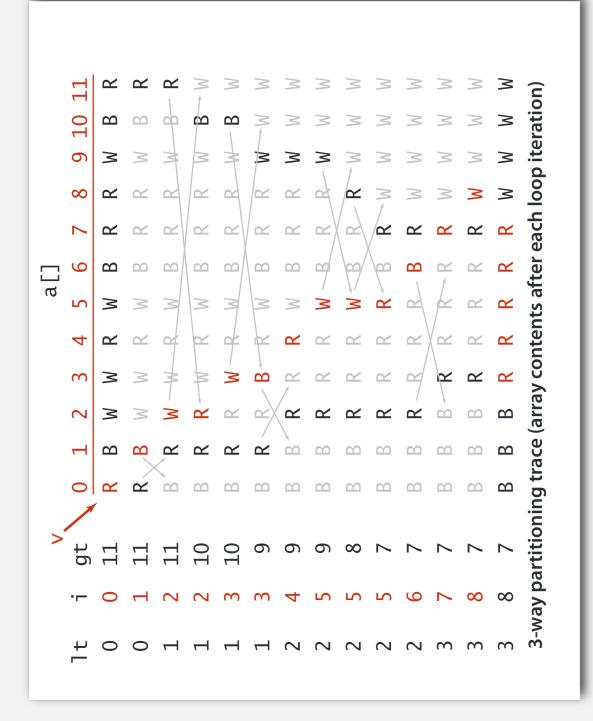

Dijkstra 3-way partitioning demo

- Let v be partitioning item a[lo].
- Scan i from left to right.
- (a[i] < v): exchange a[lt] with a[i]; increment both lt and i
- (a[i] > v): exchange a[gt] with a[i]; decrement gt
- (a[i] == v): increment i

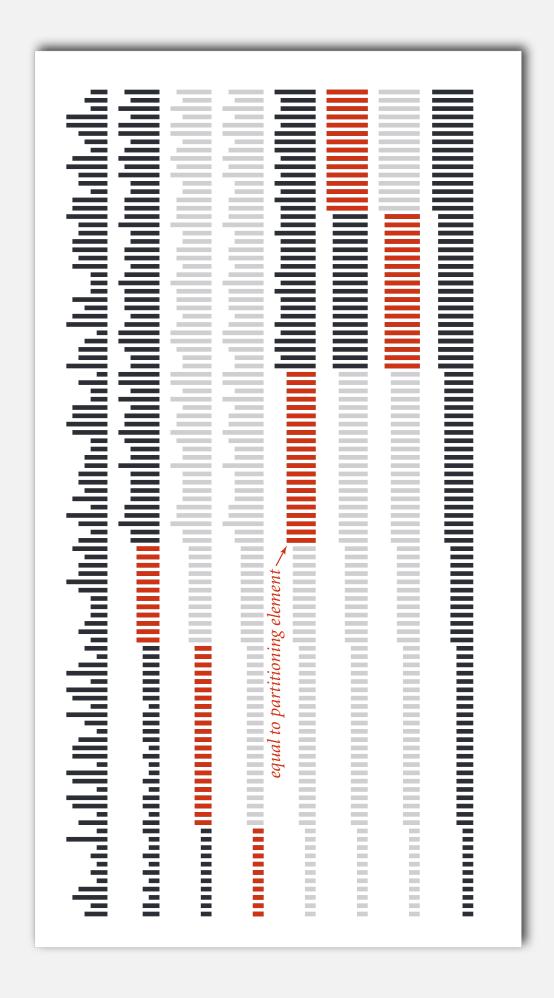

Dijkstra's 3-way partitioning: trace

3-way quicksort: Java implementation

```
private static void sort(Comparable[] a, int lo, int hi)
                                                                                                                                                                                                                                                                                                                                                                                       >
                                                                                                                                                                                                                                                                                                                                                                                                                                                  >
                                                                                                                                                                                                                                                                                                                                                                                      during
                                                                                                                                                                                                                     if (cmp < 0) exch(a, lt++, i++);

```

Q. Why use different algorithms for primitive and reference types?

War story (C qsort function)

AT&T Bell Labs (1991). Allan Wilks and Rick Becker discovered that a qsort() call that should have taken seconds was taking minutes.

At the time, almost all qsort() implementations based on those in:

- * Version 7 Unix (1979): quadratic time to sort organ-pipe arrays.
- * BSD Unix (1983): quadratic time to sort random arrays of 0s and 1s.

Engineering a system sort

Basic algorithm = quicksort.

- Cutoff to insertion sort for small subarrays.
- * Partitioning scheme: Bentley-McIlroy 3-way partitioning.
- * Partitioning item.
- small arrays: middle entry
- medium arrays: median of 3
- large arrays: Tukey's ninther [next slide]

Engineering a Sort Function

JON L. BENTLEY

M. DOUGLAS McILROY

AT&T Bell Laboratories, 600 Mountain Avenue, Murray Hill, NJ 07974, U.S.A.

SUMMARY

We recount the history of a new <code>qsortfunction</code> for a C library. Our function is clearer, faster and more robust than existing sorts. It chooses partitioning elements by a new sampling scheme; it partitions by a novel solution to Dijkstra's Dutch National Flag problem; and it swaps efficiently. Its behavior was assessed with timing and debugging testbeds, and with a program to certify performance. The design techniques apply in domains beyond sorting.

Now widely used. C, C++, Java 6,

Tukey's ninther

Tukey's ninther. Median of the median of 3 samples, each of 3 entries.

- * Approximates the median of 9.
- * Uses at most 12 compares.

nine evenly spaced entries		medians	ninther

- Q. Why use Tukey's ninther?
- A. Better partitioning than random shuffle and less costly.

Achilles heel in Bentley-McIlroy implementation (Java system sort)

- Q. Based on all this research, Java's system sort is solid, right?
- A. No: a killer input.
- Overflows function call stack in Java and crashes program.
- Would take quadratic time if it didn't crash first.

System sort: Which algorithm to use?

Many sorting algorithms to choose from:

Internal sorts.

- * Insertion sort, selection sort, bubblesort, shaker sort.
- Quicksort, mergesort, heapsort, samplesort, shellsort.
- Solitaire sort, red-black sort, splaysort, Yaroslavskiy sort, psort, ...

External sorts. Poly-phase mergesort, cascade-merge, oscillating sort.

String/radix sorts. Distribution, MSD, LSD, 3-way string quicksort.

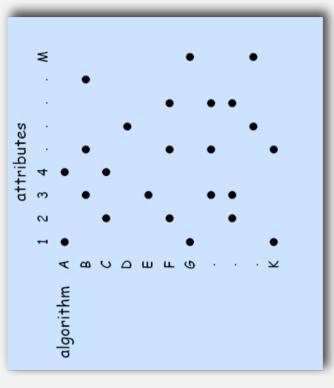

Parallel sorts.

- Bitonic sort, Batcher even-odd sort.
- Smooth sort, cube sort, column sort.
- × GPUsort.

System sort: Which algorithm to use?

Applications have diverse attributes.

- stable?
- Parallel?
- Deterministic?
- Keys all distinct?
- Multiple key types?
- Linked list or arrays?
- Large or small items?
- Is your array randomly ordered?
- Need guaranteed performance?

many more combinations of attributes than algorithms

Elementary sort may be method of choice for some combination.

- Cannot cover all combinations of attributes.
- Q. Is the system sort good enough?
- A. Usually.
